Genome Assembly & Alignment Primer

Michael Schatz

Sept 27, 2012 Beyond the Genome

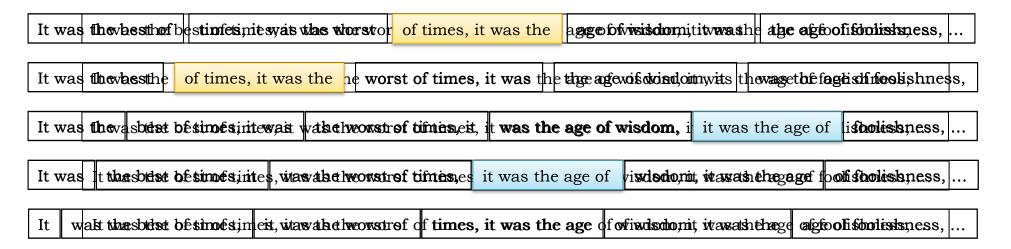

Outline

- I. Assembly by Analogy
- 2. Genome Assembly
 - I. Coverage, read length, repeats, and errors
 - 2. Genome assemblers & Assemblathon
- 3. Whole genome alignment

Shredded Book Reconstruction

- Dickens accidentally shreds the first printing of A Tale of Two Cities
 - Text printed on 5 long spools

- How can he reconstruct the text?
 - 5 copies x 138, 656 words / 5 words per fragment = 138k fragments
 - The short fragments from every copy are mixed together
 - Some fragments are identical

It was the best of age of wisdom, it was best of times, it was it was the age of it was the age of it was the worst of of times, it was the of times, it was the of wisdom, it was the the age of wisdom, it the best of times, it the worst of times, it times, it was the age times, it was the worst was the age of wisdom, was the age of foolishness, was the best of times, was the worst of times, wisdom, it was the age worst of times, it was

Greedy Reconstruction

```
It was the best of

was the best of times,

the best of times, it

best of times, it was

of times, it was the

of times, it was the

times, it was the worst

times, it was the age
```

The repeated sequence make the correct reconstruction ambiguous

• It was the best of times, it was the [worst/age]

Model the assembly problem as a graph problem

de Bruijn Graph Construction

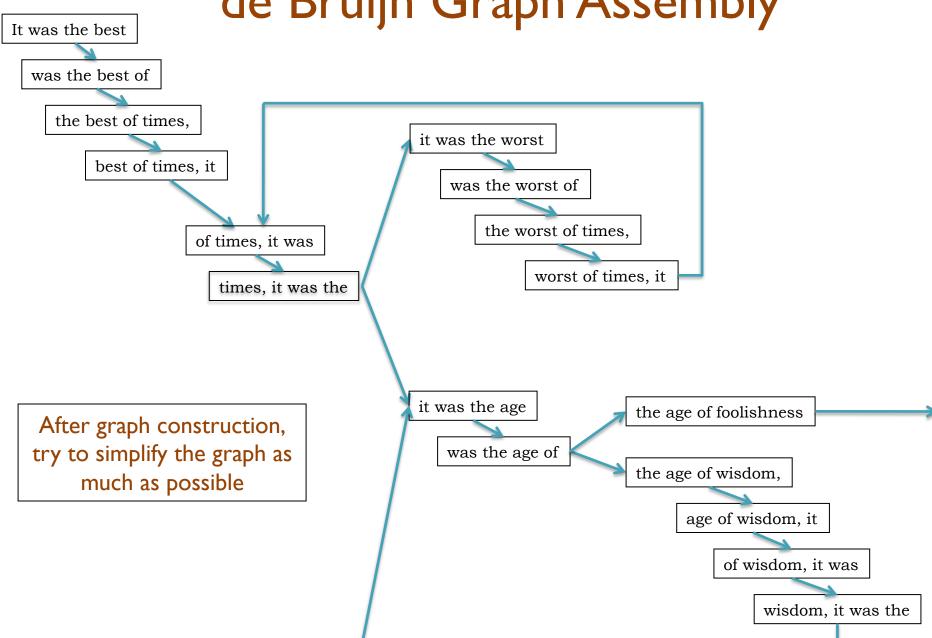

- $D_k = (V,E)$
 - V = All length-k subfragments (k < l)
 - E = Directed edges between consecutive subfragments
 - Nodes overlap by k-1 words

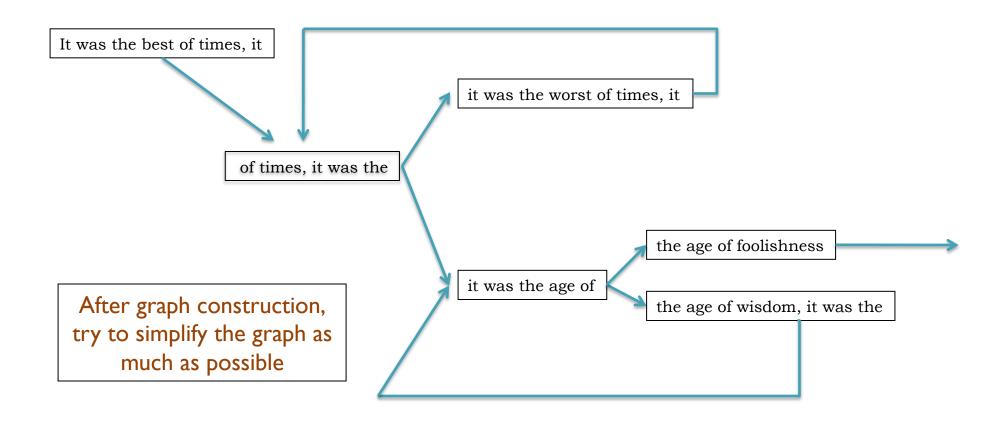

- Locally constructed graph reveals the global sequence structure
 - Overlaps between sequences implicitly computed

de Bruijn, 1946 Idury and Waterman, 1995 Pevzner, Tang, Waterman, 2001

de Bruijn Graph Assembly

de Bruijn Graph Assembly

Assembly Applications

Novel genomes

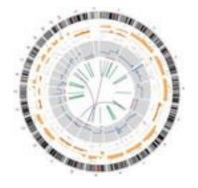

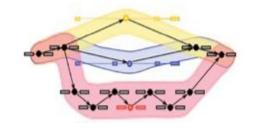

Metagenomes

- Sequencing assays
 - Structural variations
 - Transcript assembly

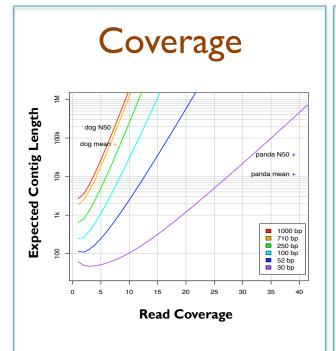

— ...

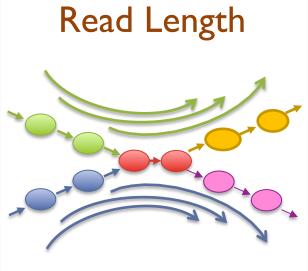

Like Dickens, we must computationally reconstruct a genome from short fragments

Ingredients for a good assembly

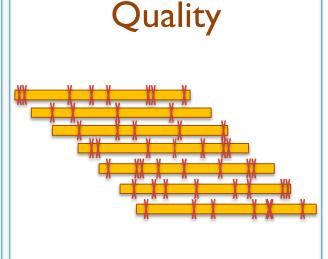

High coverage is required

- Oversample the genome to ensure every base is sequenced with long overlaps between reads
- Biased coverage will also fragment assembly

Reads & mates must be longer than the repeats

- Short reads will have false overlaps forming hairball assembly graphs
- With long enough reads, assemble entire chromosomes into contigs

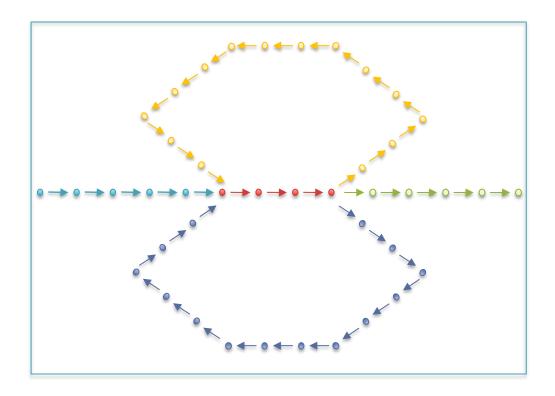

Errors obscure overlaps

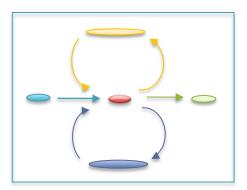

- Reads are assembled by finding kmers shared in pair of reads
- High error rate requires very short seeds, increasing complexity and forming assembly hairballs

Current challenges in de novo plant genome sequencing and assembly Schatz MC, Witkowski, McCombie, WR (2012) Genome Biology. 12:243

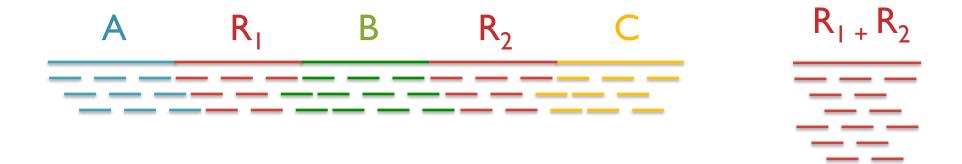

Initial Contigs

- After constructing assembly graph, compress graph down to its non-branching initial contigs
 - Aka "unitigs", "unipaths"

Repeats and Coverage Statistics

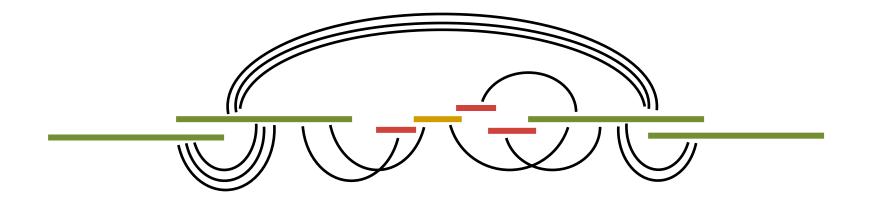

- If *n* reads are a uniform random sample of the genome of length *G*, we expect $k=n\Delta/G$ reads to start in a region of length Δ .
 - If we see many more reads than k (if the arrival rate is > A), it is likely to be a collapsed repeat
 - Requires an accurate genome size estimate

$$\Pr(X - copy) = \binom{n}{k} \left(\frac{X\Delta}{G}\right)^k \left(\frac{G - X\Delta}{G}\right)^{n-k} \qquad A(\Delta, k) = \ln\left(\frac{\Pr(1 - copy)}{\Pr(2 - copy)}\right) = \ln\left(\frac{\frac{(\Delta n/G)^k}{k!} e^{\frac{-\Delta n}{G}}}{\frac{(2\Delta n/G)^k}{k!} e^{\frac{-2\Delta n}{G}}}\right) = \frac{n\Delta}{G} - k \ln 2$$

Scaffolding

- Initial contigs (aka unipaths, unitigs) terminate at
 - Coverage gaps: especially extreme GC regions
 - Conflicts: sequencing errors, repeat boundaries
- Iteratively resolve longest, 'most unique' contigs
 - Both overlap graph and de Bruijn assemblers initially collapse repeats into single copies
 - Uniqueness measured by a statistical test on coverage

N50 size

Def: 50% of the genome is in contigs larger than N50

N50 size = 30 kbp
$$(300k+100k+45k+45k+30k = 520k >= 500kbp)$$

Note:

N50 values are only meaningful to compare when base genome size is the same in all cases

Assembly Algorithms

ALLPATHS-LG

A(1) D(1) E(2) G(1)

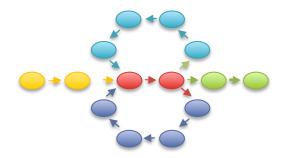

Broad's assembler (Gnerre et al. 2011)

De bruijn graph
Short + PacBio (patching)

Easy to run if you have compatible libraries

http://www.broadinstitute.org/ software/allpaths-lg/blog/

SOAPdenovo

BGI's assembler (Li et al. 2010)

De bruijn graph Short reads

Most flexible, but requires a lot of tuning

http://soap.genomics.org.cn/ soapdenovo.html

Celera Assembler

JCVI's assembler (Miller et al. 2008)

Overlap graph

Medium + Long reads

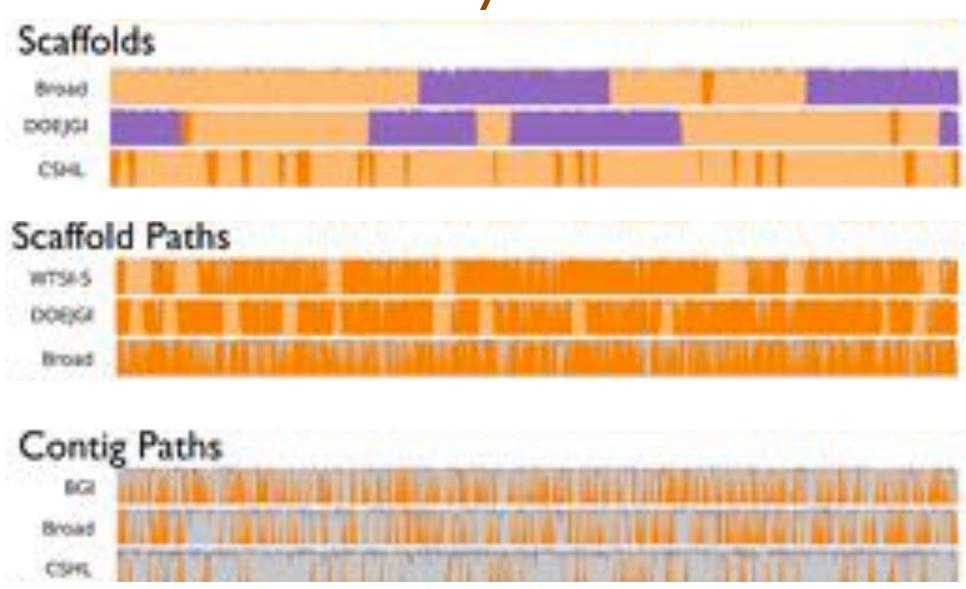

Supports Illumina/454/PacBio Hybrid assemblies

http://wgs-assembler.sf.net

- Attempt to answer the question:
 "What makes a good assembly?"
- Organizers provided simulated sequence data
 - Simulated 100 base pair Illumina reads from simulated diploid organism
- 41 submissions from 17 groups
- Results demonstrate trade-offs assemblers must make

Assembly Results

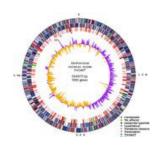

Final Rankings

- SOAPdenovo and ALLPATHS came out neck-and-neck followed closely behind by SGA, Celera Assembler, ABySS
- My recommendation for "typical" short read assembly is to use ALLPATHS

Assembly Summary

Assembly quality depends on

- 1. Coverage: low coverage is mathematically hopeless
- 2. Repeat composition: high repeat content is challenging
- 3. Read length: longer reads help resolve repeats
- 4. Error rate: errors reduce coverage, obscure true overlaps
- Assembly is a hierarchical, starting from individual reads, build high confidence contigs/unitigs, incorporate the mates to build scaffolds
 - Extensive error correction is the key to getting the best assembly possible from a given data set
- Watch out for collapsed repeats & other misassemblies
 - Globally/Locally reassemble data from scratch with better parameters & stitch the 2 assemblies together

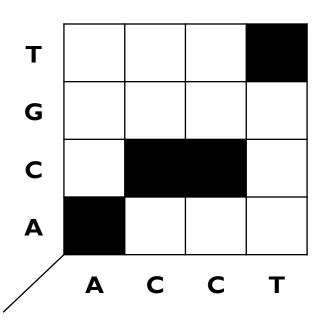

Whole Genome Alignment with MUMmer

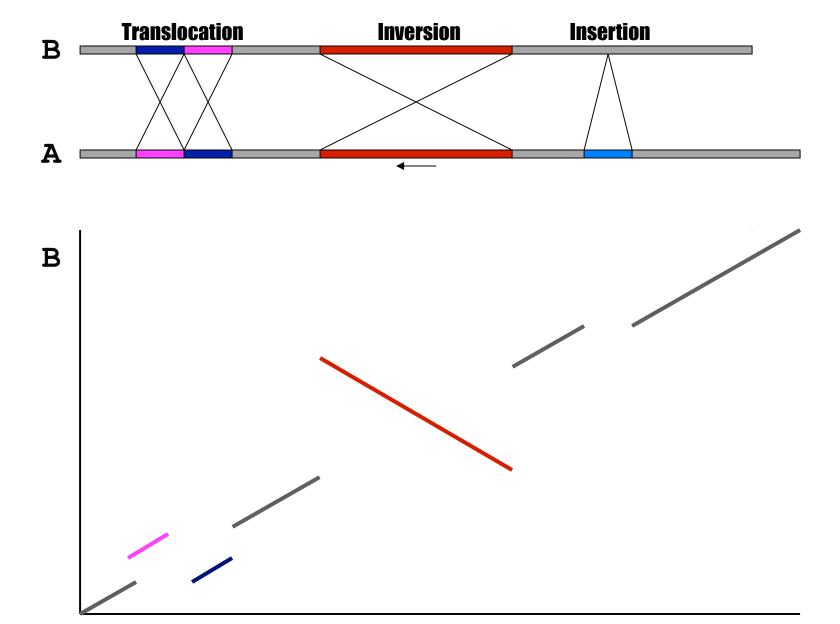

Slides Courtesy of Adam M. Phillippy amp@umics.umd.edu

WGA visualization

- How can we visualize whole genome alignments?
- With an alignment dot plot
 - $-N \times M$ matrix
 - Let *i* = position in genome *A*
 - Let j = position in genome B
 - Fill cell (i,j) if A_i shows similarity to B_i

 A perfect alignment between A and B would completely fill the positive diagonal

Seed and Extend

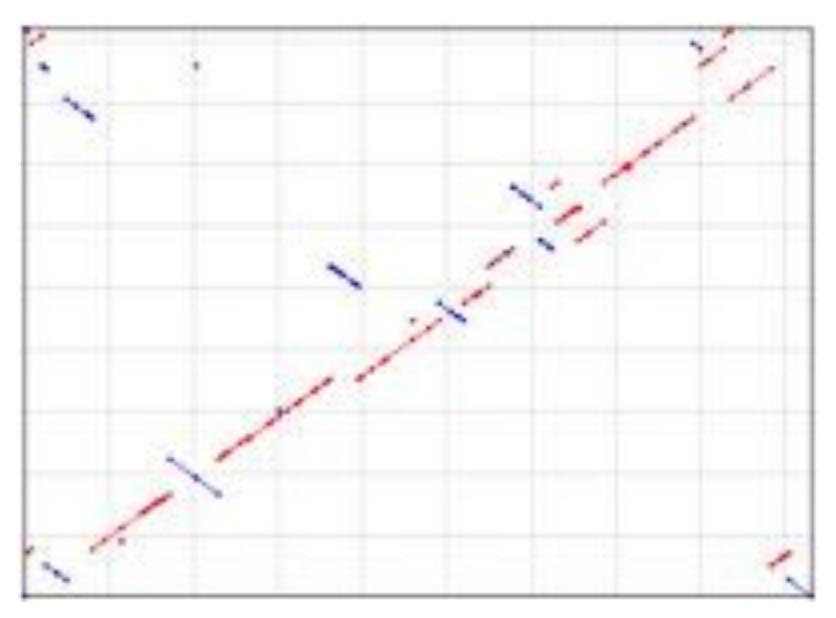

How can quickly find large alignments?

- I. Find short exact matches
 - using a suffix tree
- 2. Cluster exact matches
 - using size, gap and distance parameters
- 3. Extend clusters & report alignments
 - using modified Smith-Waterman algorithm

WGA example with nucmer

Yersina pestis CO92 vs. Yersina pestis KIM

- High nucleotide similarity, 99.86%
 - Two strains of the same species
- Extensive genome shuffling and highly repetitive
 - Global alignment will not work
